ABSTRACT

This research work is centered on 2D seismic reflection data and well logs of Sanghar area, Sindh province, Pakistan. Seven seismic sections having line numbers (856-SGR-54, 856-SGR-58, 856-SGR-63, 856-SGR-55, 856-SGR-53, 856-SGR-65 and 856-SGR-67) along with base map were used. Out of these seven seismic lines, two seismic lines; 856-SGR-54 and 856-SGR-58 are dip lines. The remaining lines are strike lines. Root mean square and interval velocities of some sections are also provided with the seismic section at selected Common Depth Points (CDP's) and were used for the calculation of average velocities to convert the given time into depth. Synthetic seismogram of Bobi-01 well was made to match the reflectors on the seismic section. Four formations were correlated with seismic section. Khadro Formation was matched at 0.5 sec, Parh Limestone at 0.7 sec, Top of Lower Goru at 1.2 sec and Chiltan Limestone at 2.4 sec. The ratio of the best correlation between seismic and synthetic was 0.094. On the basis of the synthetic seismogram the reflectors were marked which further confirm the well tops. Due to the prominent reflection on the seismic sections, four reflectors were marked. For each reflector the two way travel time structural map has been drawn and depth contour map of probable reservoir has also been drawn by using velocity and one way travel time. This study shows Horst and Graben structure along with step faults. On the basis of attribute analysis bright spots are identified for the well location. The petrophysical evaluation of Bobi-01 splits into four zones every zone has shown different petrophysical result but all of these zones have good hydrocarbon saturation like zone-01 with 37% and zone-03 with 45% hydrocarbon saturation. The zones are marked on the basis of clean formation which further confirms the presence of sand in these zones. The maximum porosity in these zones is 20 to 24%. Well correlation of Al-Hakeem-01 and Bobi-01 shows that there is thinning effect from south to north and also the maturity level in Bobi-01 is more than that of Al-Hakeem-01 and also there is a gap in Al-Hakeem-01 as two formations are missing in this well.

ACKNOWLEDGEMENTS

I am deeply obligated to my supervisor Prof. Dr. Tahseenullah Khan Bangash (Bahria University, Department of Earth and Environmental Sciences, Islamabad) and my Co-supervisor Mr. Muyassar Hussain, Geoscientist (Landmark Resources) whose help, stimulating ideas, information, experience and encouragement helped me in all the times of study and analysis of the project. I would also like to thank Ahmer Iqbal and Waqar Ahmed for their guidance and help. Marks are also extended to Landmark Resources (LMKR) and Directorate General of Petroleum Concession (DGPC) for providing data.

Last but not the least I am indebted to Prof. Dr. Muhammad Zafar (HOD, Bahria University, E&ES Department, Islamabad) and Mr. Saqib Mehmood, Assistant professor (Bahria University, E&ES Department, Islamabad) for their moral support and guidance and to my parents for their prayers and encouragement during my whole studies.
